Project Name	The Customer Support Ticket Priority Prediction and Automated Assignment System using Agentforce
Maximum Marks	

Project Development

The development of the Customer Support Ticket Priority Prediction and Automated Assignment System using Agentforce is carried out on the Salesforce platform. The main objective of the development process is to automate support-ticket analysis, priority prediction, task creation, agent assignment, and SLA risk identification.

1. Salesforce Environment Setup

The project is developed using a Salesforce Developer Org. The Salesforce environment is configured with the required users, permissions, objects, fields, Flow, and Agentforce components.

The development environment provides the required platform for creating the custom support-ticket object and implementing automation. Appropriate permissions are provided to administrators and support users so that they can access the required customer and ticket information.

2. Custom Object Development

A custom object named Support Ticket Intelligence is created to store customer support information.

API Name: Support_Ticket_Intelligence__c

The object contains important fields such as:

Ticket Number

Customer / Account

Contact

Issue Type
Description
Priority Level
Status
Created Date
Assigned To
SLA Breach Risk
Resolution Time

The custom object allows support-ticket information to be stored in a structured manner and provides relationships with standard Salesforce objects such as Account, Contact, and User.

3. Data Model Development

The system uses Salesforce standard and custom objects to maintain relationships between customer and ticket information.

Account

The Account represents the customer organization, while Contact stores the individual customer information. The Support Ticket Intelligence object stores the actual support issue. The User object identifies the assigned support agent, and Task records are created for follow-up activities.

4. Ticket Description Analysis

The ticket description is analyzed to identify the urgency of the customer issue. The system uses configured keywords and conditions to classify tickets.

For example:

Condition	Priority
urgent, not working, failure	High
issue, slow, delay	Medium
No matching condition	Low

This provides a simple and consistent method for initial priority classification.

5. Auto-Launched Flow Development

An Auto-Launched Flow is developed to automate the backend processing.

The Flow receives the Account Name as an input and retrieves the latest support ticket associated with that Account.

The major Flow steps are:

Get Account.

Store Account ID.

Get the latest Support Ticket.

Store Ticket ID.

Analyze the ticket description.

Determine ticket priority.

Check whether the ticket is High priority.

Create a Task for High-priority tickets.

Assign the appropriate support level.

Check SLA risk.

Generate the final action message.

Return the output to Agentforce.

6. Priority Prediction

The Flow Decision element is used to determine whether the ticket is High, Medium, or Low priority.

High-priority tickets are treated as urgent cases. Medium-priority tickets are handled through normal support processing, while Low-priority tickets are queued for regular processing.

This automation reduces the need for support agents to manually review every ticket for basic priority classification.

7. Automated Task Creation

When a ticket is classified as High priority, the Flow automatically creates a Salesforce Task.

Example:

Subject: Urgent Ticket Handling

Priority: High

Status: Not Started

Related Record: Support Ticket

This ensures that urgent tickets generate an immediate follow-up activity.

8. Automated Assignment

The system assigns high-priority tickets to an appropriate support level. For example, a High-priority ticket can be assigned to a Senior Support Agent.

This helps ensure that urgent issues are routed to the appropriate support resource without requiring manual assignment.

9. SLA Risk Checking

The solution includes an SLA risk-checking step for unresolved tickets. Older tickets can be evaluated

based on their creation date and configured SLA conditions.

If a ticket approaches its SLA limit, the system can identify it as an SLA-risk ticket and include the information in the final response.

10. Agentforce Development

Agentforce is configured as the conversational AI layer of the application.

A subagent named:

Support Ticket Priority Analysis is created to handle customer support-ticket analysis.

The Agentforce subagent can:

- Ask for the Account Name.

- Retrieve the latest support ticket.

- Analyze the ticket description.

- Determine ticket priority.

- Trigger the backend Flow.

- Identify the assigned support level.

- Return the final action message.

11. Agentforce and Flow Integration

Agentforce does not directly perform the backend record-processing activities. Instead, it invokes the configured Auto-Launched Flow.

The overall interaction is:

User

Agentforce

Support Ticket Priority Analysis

Auto-Launched Flow

Get Account

Get Latest Ticket

Analyze Description

Priority Decision

Task / Assignment / SLA Check

Final Output

Agentforce Response

This separation makes the solution easier to maintain because conversational logic is handled by Agentforce while backend processing is handled by Salesforce Flow.

12. Conversational Response

After the Flow completes its processing, the output variables are returned to Agentforce.

The response can include:

Ticket ID

Priority Level

Assigned Agent

Account ID

Action Message

SLA Risk information

For example:

High priority ticket detected. The ticket has been assigned for urgent handling and a follow-up task has been created.

This provides support agents with a clear and understandable result.

13. Testing and Validation

The developed solution is tested using different ticket descriptions to verify the priority classification and automation.

Test Case	Ticket Description	
Expected Result		
TC-01	System failure and urgent issue	High
Priority + Task Creation		
TC-02	Application is slow	
Medium Priority		
TC-03	General information request	Low Priority
TC-04	Urgent issue with Account	High Priority + Agent
Assignment		
TC-05	Older unresolved ticket	
SLA Risk identified		

Testing ensures that the Flow, Agentforce subagent, priority logic, task creation, and assignment work according to the configured requirements.

14. Final Development Outcome

The completed system provides an automated support-ticket workflow where Agentforce analyzes customer issues, Salesforce Flow determines priority, creates tasks, assigns support agents, checks SLA risk, and returns the final result conversationally.

The solution reduces manual processing, improves consistency in ticket handling, supports faster response to critical issues, and provides a scalable foundation for future enhancements such as advanced AI-based classification, dashboards, notifications, and additional Agentforce actions.
